One-minute summary

- Using modelling and longitudinal sampling, the authors tested whether acute B.1.1.7 infection is associated with higher or more sustained nasopharyngeal (NP) viral concentrations.
- A regression model was used to determine the mean duration of viral RNA shedding for B.1.1.7 (n=7) and non-B.1.1.7 (n=58) cases:
 - **Proliferation phase, days (90% credible interval [CrI]):** 5.3 (2.7–7.8) vs. 2.0 (0.7–3.3)
 - **Clearance phase, days (90% CrI):** 8.0 (6.1–9.9) vs. 6.2 (5.1–7.1)
 - **Overall duration, days (90% CrI):** 13.3 (10.1–16.5) vs. 8.2 (6.5–9.7)
- Mean peak viral concentration for B.1.1.7 (n=7) and non-B.1.1.7 (n=58) cases:
 - **Cycle threshold (Ct) values (90% CrI):** 19.0 (15.8–22.0) vs. 20.2 (19.0–21.4)
 - **Log₁₀ RNA copies/ml (90% CrI):** 8.5 (7.6–9.4) vs. 8.2 (7.8–8.5)
- Based on the preliminary data, the authors concluded that **B.1.1.7 may cause longer infections** with similar peak viral concentration compared to non-B.1.1.7, potentially contributing to increased transmissibility.

Additional information

- The study population represented a convenience sample including staff and players of a professional sports league who underwent daily Coronavirus Disease 2019 (COVID-19) testing of combined anterior nares and oropharyngeal swabs by real-time reverse transcription polymerase chain reaction (RT-PCR).
- There was an initial pool of 298 patients who tested positive by RT-PCR from November 28, 2020 to January 20, 2021. Among these, only cases with “novel” infection (i.e., likely new infection) were included in the current study. B.1.1.7 cases were identified by whole genome sequencing.
- Duration of viral proliferation and clearance were estimated by statistical modelling:

Review of “Densely sampled viral trajectories suggest longer duration of acute infection with B.1.1.7 variant relative to non-B.1.1.7 SARS-CoV-2”

- Proliferation phase is the time from first detectable virus to peak viral concentration.
- Clearance phase is the time from peak viral concentration to initial return to the limit of detection threshold.
- Viral concentration was assumed to grow exponentially during the proliferation phase and decay exponentially during the clearance phase.

PHO reviewer's comments

- A positive RT-PCR may or may not represent the presence of live or infectious virus, as the RNA detected potentially only represents the presence of fragmented or residual viral particles. Only seven cases with the B.1.1.7 variant were included. No comparison was provided between B.1.1.7 and non-B.1.1.7 cases for other factors that may affect the period of communicability such as demographic factors (E.g., age) and clinical features (E.g., symptoms or severity). Future study should concentrate on larger sample sizes to provide generalizable findings and include detection of live virus.
